MARKET SEGMENTATION | 12.12.2024 | TEAM AWESOME

Where to open a cafe in Toronto?

Toronto boasts a diverse array of neighborhoods, each with its own unique charm and characteristics.

The goal was to identify a neighborhood that provides optimal business opportunities, a robust customer base, and minimal competition.

OBJECTIVE

The objective was to analyze the distribution of markets, assess the existing competition, evaluate the population density and median household income within each neighborhood.

How can I find reliable sources for population and income data?

Which API service best meets our needs?

Which statistical analysis method is best suited for analyzing categorical data?

PROJECT OVERVIEW

THE RECOMMENDATIONS

Rouge Hill/Port Union/Highland Creek

This neighborhood in **Scarborough** experiences high foot traffic due to the presence of numerous transit stations, offices, and gas stations, all of which can significantly boost sales for a cafe.

Population
35,642
Median Household Income
$ 109,785

Lawrence Park

This neighborhood in **Central Toronto** enjoys high foot traffic due to the numerous businesses, offices, clinics, and shopping plazas, all of which is good for cafe sales.

Population
16,058
Median Household Income
$ 137,758

Milliken / Agincourt North / Steeles East

This neighborhood in **Scarborough** experiences high foot traffic due to the presence of numerous transit stations, offices, shopping plazas, churches, all of which these will help the sales of a cafe.

Population
50,825
Median Household Income
$ 64,576

Median Per postal code Population - 26128 census year 2021
Median Per postal code Income - $65508 census year 2021
Median Per postal code Count of cafes - 1 Google Nearby Places

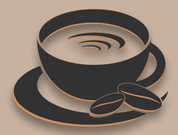
METHODOLOGY

Our Approach

A commentary, describing the steps enabling the analysis.

WEB SCRAPING AND SECONDARY DATA SOURCES

1. **Scrape Postal Code Data**
   Scrape postal code data of Toronto from Wikipedia.
   Clean and save the postal code data into a data frame.
   Verify if all postal codes are obtained.
2. **Add Geographical Data**
   Add latitude and longitude using pgeocode.
   Inspect, discuss, and clean the geo data for data sanity.
3. **Population Data**
   Download the population csv from Statistics Canada.
   Extract Toronto-specific data from the csv and save it.
   Read the new csv and save the population data frame.
4. **Income Data**
   Download the income csv from Statistics Canada.
   Extract Toronto-specific data from the csv and save it.
   Read the new csv and save the income data frame.
5. **Merge Data**
   Merge the postal-geo data, population data, and income data into a master data frame (**toronto_data**)
6. **Inspect and Clean Master Data**
   Step description
7. **Visual Representation**
   Plot the richest and most populous postal codes for visual representation.
8. **Measure central Tendencies**
   Box Plot Population, Income, Cafe counts
   Discuss to calculate either Mean or Median
   Calculate the Medians



API CALLS AND RE-USEABLE FUNCTIONS

9

API Selection

Analyze Google Places and Foursquare Places.
Set up an API call, read response, read the documentation.

10

Function to get Required Dictionary

Get all Place Type Cafe from the responses.
Use **get_places_cafe** function, append to **toronto_data.**

11

Data Storage

Store the responses as a csv.
Read the csv and create **toronto_data_df**
Store postal codes, geo information, income, population, counts of cafes, and names of cafes.

12

Visualization MAP

Plot toronto_data_df on a map to enable visualization of cafe competition.

13

Function Iteration

Iterate the function into **get_places_all** to get all place types for postal codes.

14

Data Filtering, Function Iteration 2

Iterate **get_places_all** to filter out places with 'point_of_interest' as the first in type list and get the second type if available (this place type is not of business use).

15

Final Data Storage

Store the response as a csv so that no more API calls are needed while working.
Read the csv and create a data frame **toronto_data_places**.

ONE-HOT ENCODING AND K-MEANS

16

One-Hot Encoding

Perform **one-hot encoding on the 'Place Type'** column to prepare categorical data for the machine learning model.

17

Grouping and Analysis

Group by 'Postal Code' and calculate the mean of each one-hot encoded column to analyze the distribution of different place types across various postal codes in Toronto.
Identify the most common place types for each postal code in Toronto as frequencies.

18

Function Creation for Common Places

Create a function to identify the most common places for rows in the coded and grouped Data Frame, make a **lists of top 10 most common places for each postal code.**

19

Clustering

Use **Silhouette Score** to establish the number of clusters.
Set up and run the **K-means clustering algorithm.**

20

Final Data Frame

Final Data Frames using, dropping columns not necessary for conclusion and discussion. **Display all 4 clusters.**
Plot **Stacked Bar Chart**

21

Cluster Selection

Select the most suitable cluster for the cafe business environment using the stacked bar charts.

22

Prime Location In the cluster

Score the postal codes for Population and Income and sort the result to get the Top 3.

THE REPORT

Here is the data analysis report resulting from the market segmentation study.

CENTRAL TENDENCIES

Median Per postal code Population - 26128 census year 2021
Median Per postal code Income - $65508 census year 2021
Median Per postal code Count of cafes - 1 Google Nearby Places

Population:

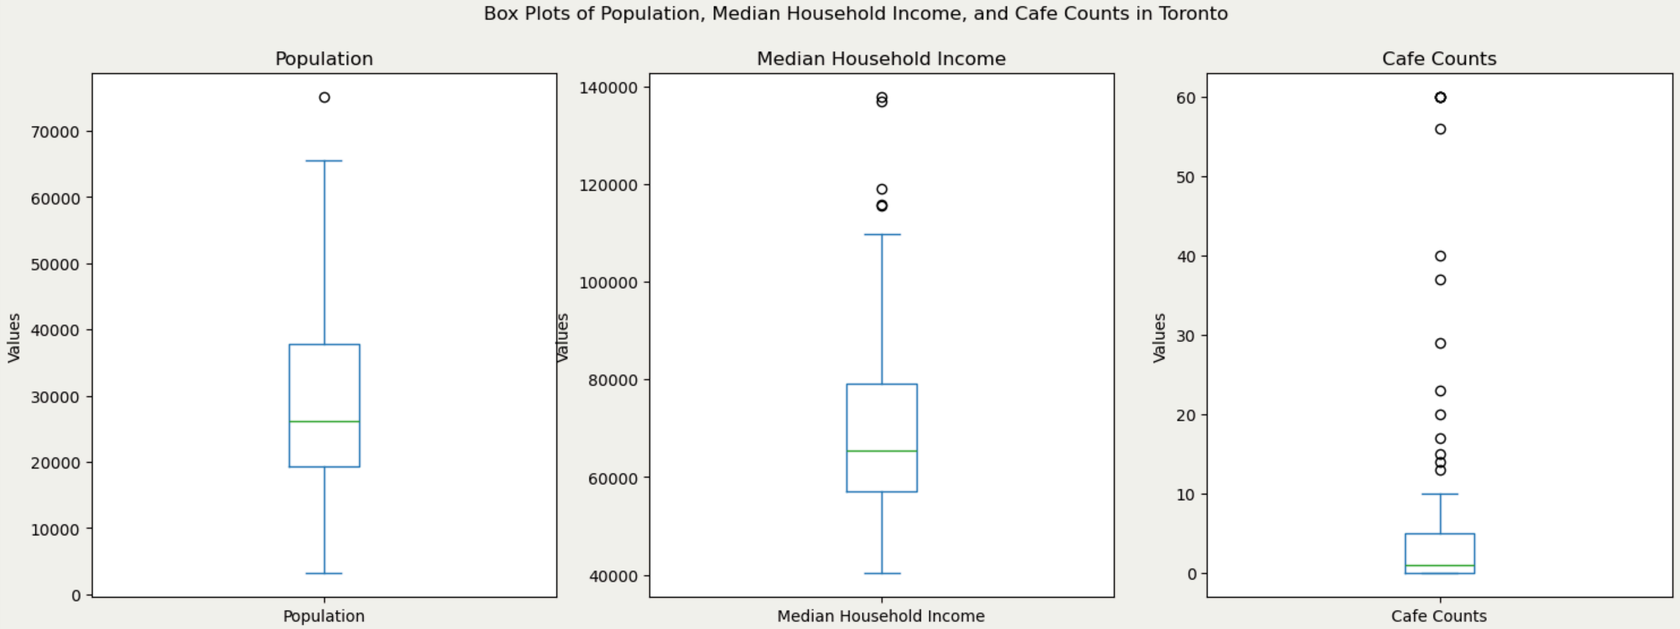
The median is around 25,000.
IQR spans from 15,000 to 40,000.
There is one outlier above 70,000.

Median Household Income:

The median is around 60,000.
IQR spans from 50,000 to 80,000.
There are several outliers above 100,000.

Cafe Counts:

The median is around 2.
IQR spans from 1 to 6.
There are numerous outliers above 10, with the highest being around 60.



CLUSTERS

Cluster A:

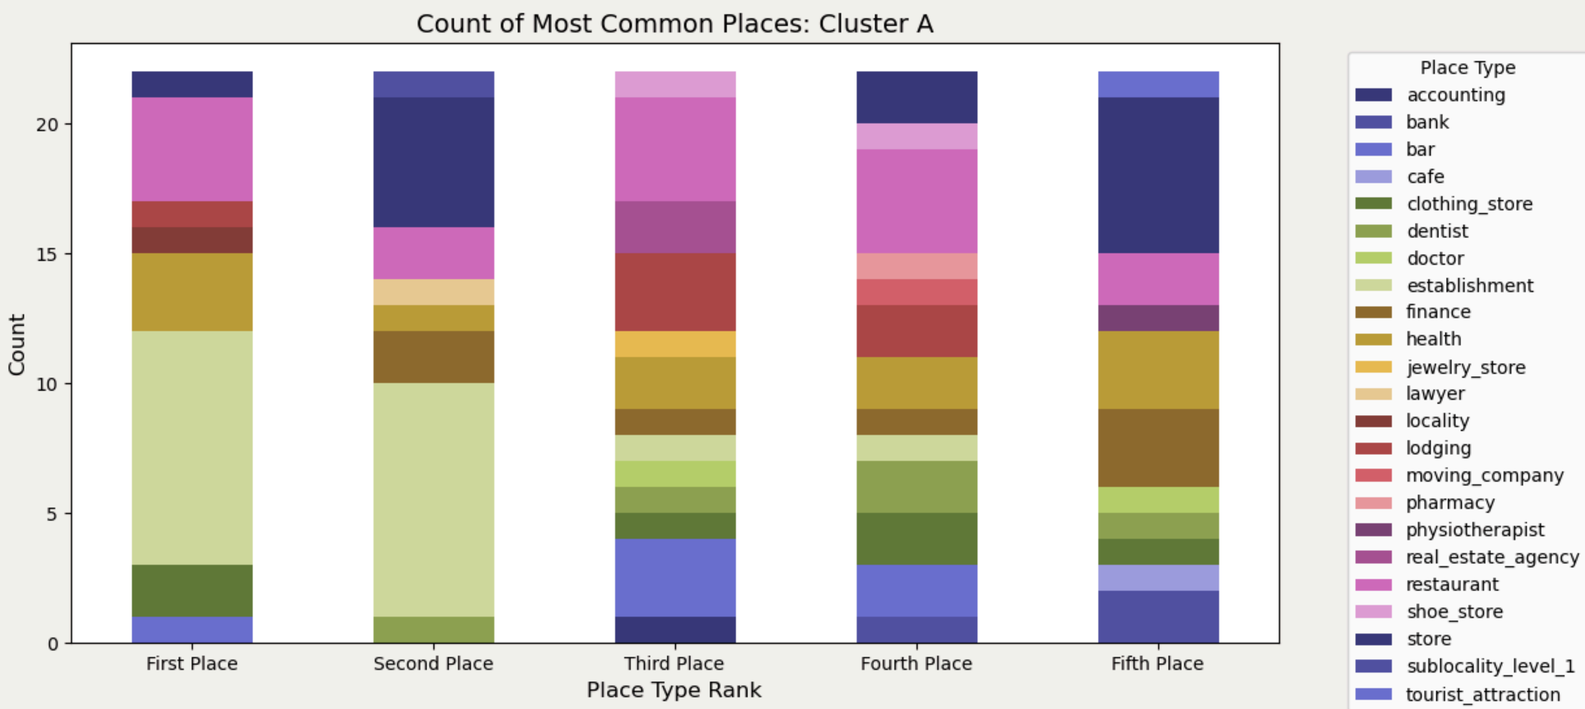
A Business heavy area with restaurants and motels.

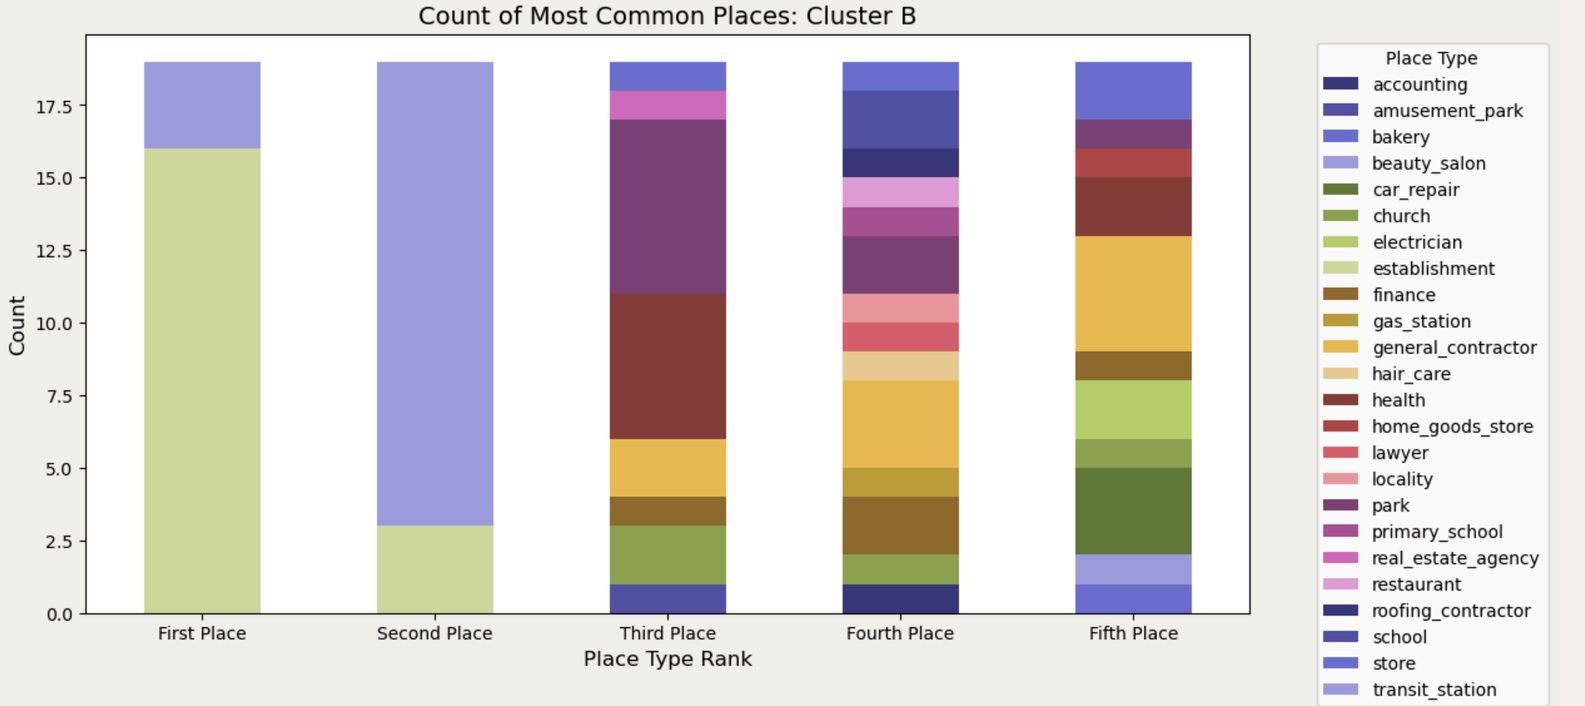
High concentration of cafes in postal codes M5B, M5C, M5E, M5G, and M5H.

Cluster B:

High footfall due to transit points, making it ideal for new cafes.

Few cafes, with small counts in postal codes M1H, M1V, and M9P.





CLUSTERS

Cluster C:

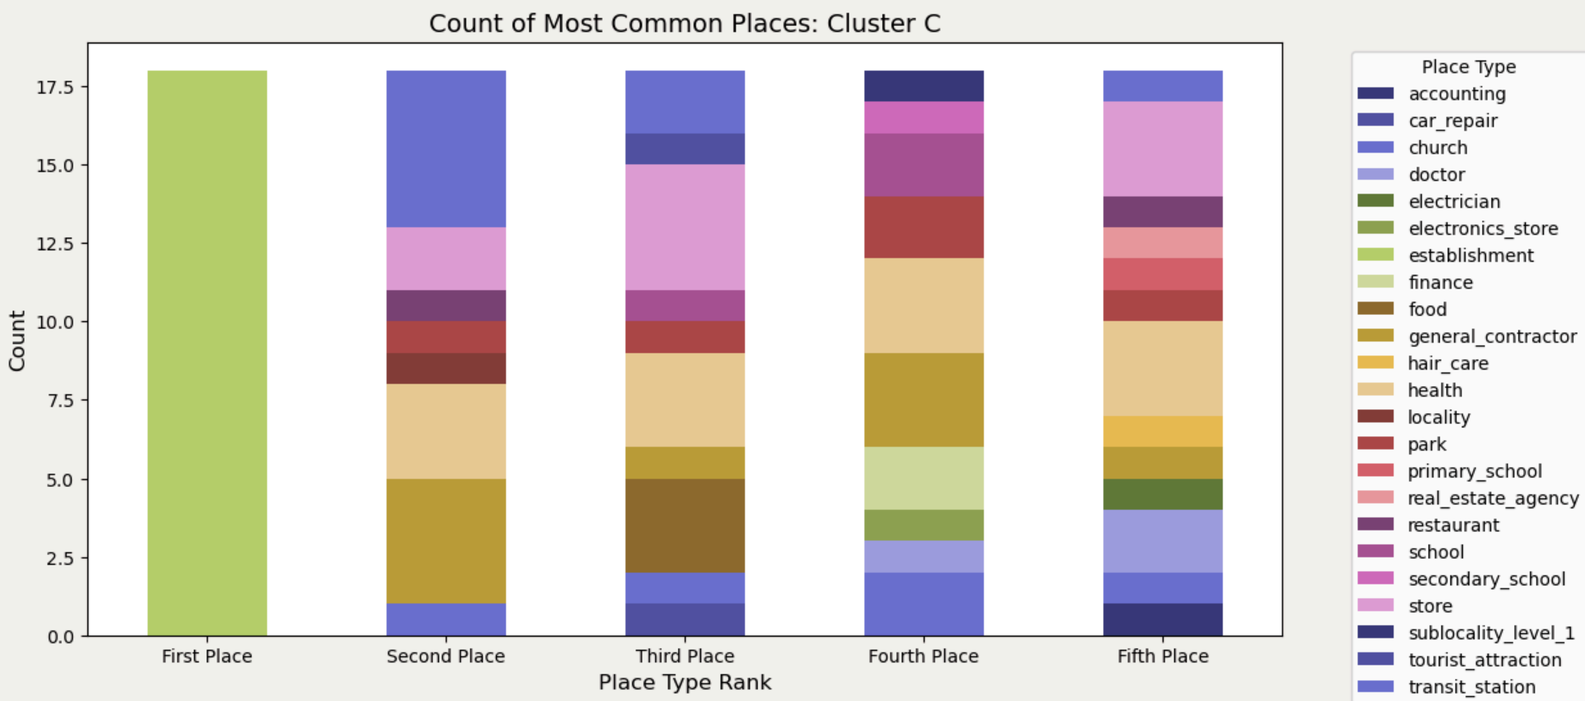
A Business heavy area with shops and doctor clinics.

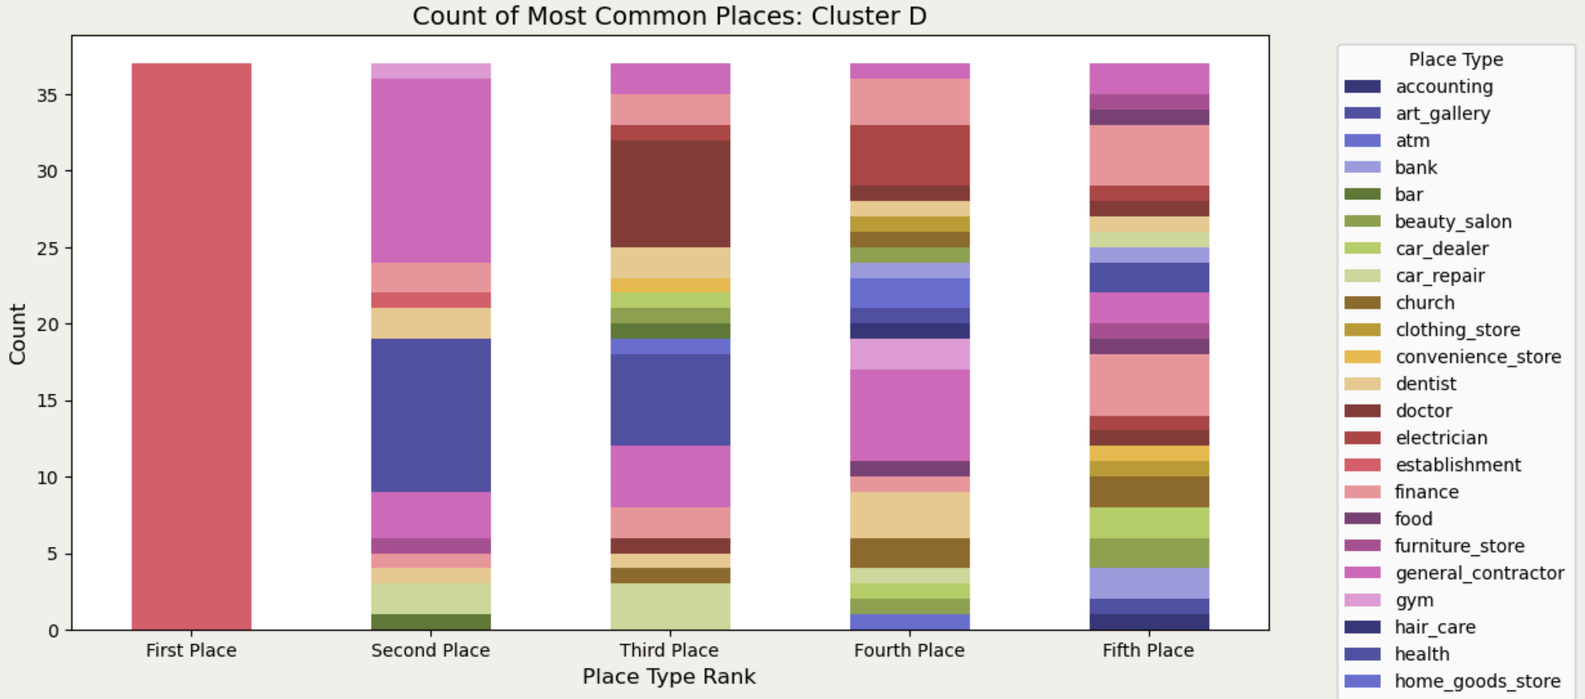
Moderate number of cafes in postal codes M3C, M4E, M5J, and M6K.

Cluster D:

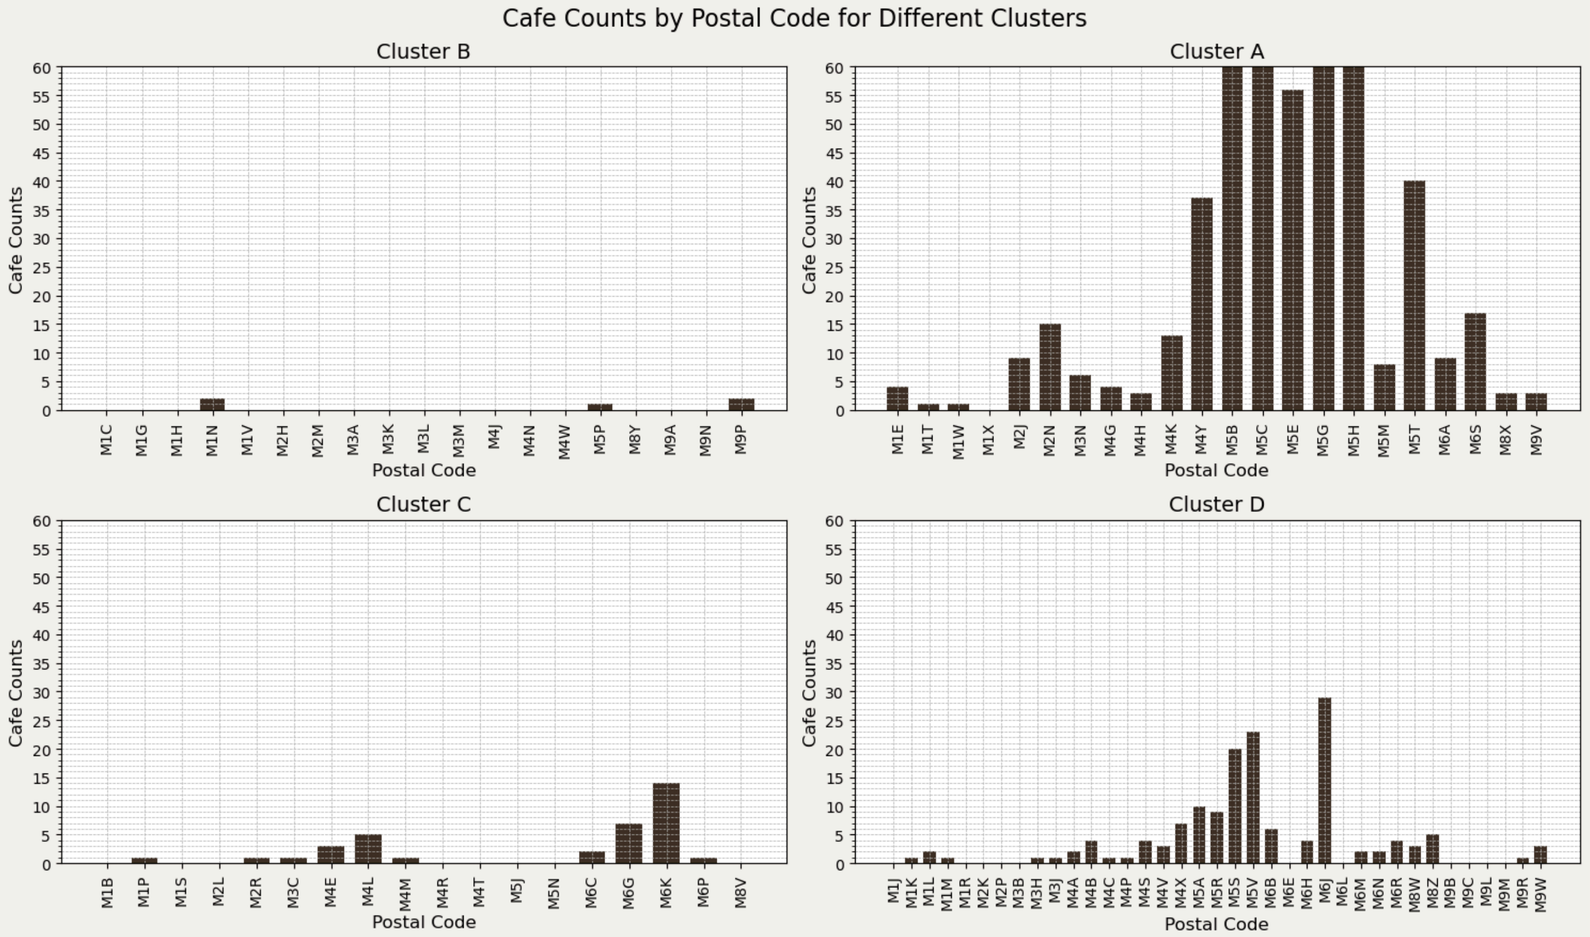
A Industrial heavy area with some shops and clinics.

Notable number of cafes in postal codes M5V, M6G, and M6H.





COMPETITION



Cluster Selection

Cluster B Is the recommended cluster as it has high volume of businesses and offices, with lots of transit points. Such high footfall will yield high cafe sale volume.

RECOMMENDATIONS

Rouge Hill / Port Union / Highland Creek

High household income: $109,785, High population: 35,642

Lawrence Park

Very high household income: $137,758, Sustainable population: 16,058

Milliken / Agincourt North / Steeles East

Comparable household income: $64,576, Very high population: 50,825

	Postal Code	Borough	Neighborhood	Population	Median Household Income	Cafe Counts	1st Most Common Place Type	2nd Most Common Place Type	3rd Most Common Place Type	4th Most Common Place Type	5th Most Common Place Type	6th Most Common Place Type	7th Most Common Place Type	8th Most Common Place Type	9th Most Common Place Type	10th Most Common Place Type	Score
Top	M1C	Scarborough	Rouge Hill / Port Union / Highland Creek	35642.0	109785.0	0	transit_station	establishment	finance	gas_station	car_repair	general_contractor	accounting	car_wash	hair_care	real_estate_agency	50758.1
Second	M4N	Central Toronto	Lawrence Park	16058.0	137758.0	0	establishment	transit_station	health	lawyer	general_contractor	accounting	spa	gym	park	food	49358.0
Third	M1V	Scarborough	Milliken / Agincourt North / Steeles East / L'...	50825.0	64576.0	0	transit_station	establishment	health	roofing_contractor	car_repair	church	finance	physiotherapist	pharmacy	primary_school	44786.9

THE CODE

Here is a showcase of our work that support the commentary of this data analysis.

Data Cleaning for Postal Code

This code shows how the combined data from Wikipedia has been separated in three columns as postal codes, borough and neighborhood.

Use of lambda function to simplify the code and put that value for the designed list.

```python
# Creating a function to loop through the html table and store the values in a separate  lists
def get_first_three_chars_and_substring(wiki):
    # Create empty lists to store the results
    postalcode_list = []
    borough_list = []
    neighborhood_list = []

    # Iterate through each column in the DataFrame
    for col in wiki:
        # Retrieve the first 3 characters of each string in the column and store in a list
        col_values = wiki[col].astype(str).apply(lambda x: x[:3]).tolist()
        postalcode_list.append(col_values)

        # Retrieve the substring from the 4th place value till the bracket open symbol "("
        substr_values = wiki[col].astype(str).apply(lambda x: x[4:x.find(' (')] if ' (' in x else x[4:]).tolist()
        borough_list.append(substr_values)

        # Retrieve the values within the brackets
        bracket_values = wiki[col].astype(str).apply(lambda x: x[x.find('(')+1:x.find(')')] if '(' in x and ')' in x else '').tolist()
        neighborhood_list.append(bracket_values)

    return postalcode_list, borough_list, neighborhood_list

# Get the first 3 characters, substrings, and bracket values of each column and store in separate lists
postalcode_list, borough_list, neighborhood_list = get_first_three_chars_and_substring(wiki)

# Flatten the lists
postalcode_flat = [item for sublist in postalcode_list for item in sublist]
borough_flat = [item for sublist in borough_list for item in sublist]
neighborhood_flat = [item for sublist in neighborhood_list for item in sublist]

# Create a DataFrame
toronto = pd.DataFrame({
    'Postal Code': postalcode_flat,
    'Borough': borough_flat,
    'Neighborhood': neighborhood_flat
})

# Drop rows where the column "Borough" has the value "Not assigned"
toronto = toronto[toronto['Borough'] != 'Not assigned']

# Display the resulting DataFrame
toronto.info()
toronto.head()
```

0.0s Open 'toronto' in Data Wrangler

```python
# Function to get all places using Google Places API
def get_places_all(latitude, longitude, radius=500, base_url=base_url):
    params = {
        "location": f"{latitude},{longitude}",
        "radius": radius,
        "key": google_key,
        "limit": 100
    }
    all_places = []
    while True:
        response = requests.get(base_url, params=params)
        if response.status_code == 200:
            data = response.json()
            places = data.get('results', [])
            all_places.extend(places)
            next_page_token = data.get('next_page_token')
            if next_page_token:
                params['pagetoken'] = next_page_token
                # Google recommends waiting a few seconds before making the next request
                time.sleep(2)
            else:
                break
        else:
            print(f"Failed to fetch data: {response.status_code}, {response.json()}")
            break

    # Filter out places with 'point_of_interest' as the first type and get the second type if available
    place_names_and_types = []
    for place in all_places:
        if place['types']:
            if place['types'][0] == 'point_of_interest' and len(place['types']) > 1:
                place_names_and_types.append((place['name'], place['types'][1]))
            elif place['types'][0] != 'point_of_interest':
                place_names_and_types.append((place['name'], place['types'][0]))
    return place_names_and_types
```

0.0s

```python
# Create a new DataFrame to store the results
toronto_data_places = pd.DataFrame(columns=['Postal Code', 'Latitude', 'Longitude', 'Place Type', 'Place Name'])

# Iterate over each row to get the number and names of places
for index, row in toronto_data.iterrows():
    if pd.notna(row['Latitude']) and pd.notna(row['Longitude']):
        places = get_places_all(row['Latitude'], row['Longitude'])
        for place_name, place_type in places:
            new_row = pd.DataFrame({
                'Postal Code': [row['Postal Code']],
                'Latitude': [row['Latitude']],
                'Longitude': [row['Longitude']],
                'Place Type': [place_type],
                'Place Name': [place_name]
            })
            toronto_data_places = pd.concat([toronto_data_places, new_row], ignore_index=True)

# Display the updated DataFrame
toronto_data_places
```

0.0s

API call function

Used googleapi to get the data on existing coffee shops in Toronto area by latitude and longitude for that,

put search parameters to get all the results for the cafes and convert that into csv file as limitation of the free api calls.

Combine those café counts with the extracted postal codes dataframe to see which coffee shops comes in which neighborhood.

Silhouette Score Method

The silhouette score is a measure of how similar an object is to its own cluster compared to other clusters. Higher silhouette scores indicate better-defined clusters.

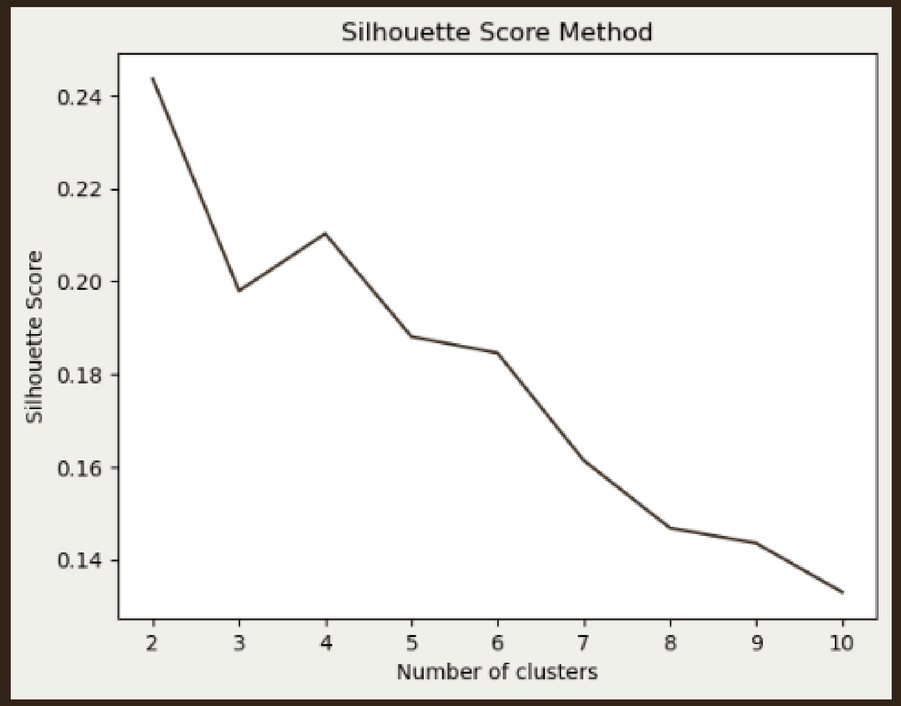
```python
# Drop the non numeric cloumn for calculations
toronto_onehot_grouped_clustering = toronto_onehot_grouped.drop('Postal Code', axis=1)

# Use your DataFrame's data
X = toronto_onehot_grouped_clustering

# Silhouette Score
silhouette_scores = []
for i in range(2, 11):  # Silhouette score is not defined for a single cluster
    kmeans = KMeans(n_clusters=i, init='k-means++', max_iter=300, n_init=10, random_state=0)
    kmeans.fit(X)
    score = silhouette_score(X, kmeans.labels_)
    silhouette_scores.append(score)

# Plot the Silhouette Scores
fig, ax = plt.subplots()
fig.patch.set_facecolor('#F4F0EC')  # Set the face color of the figure
ax.plot(range(2, 11), silhouette_scores, color='#3e3023')  # Set the color of the plotted line
ax.set_title('Silhouette Score Method')
ax.set_xlabel('Number of clusters')
ax.set_ylabel('Silhouette Score')
plt.show()
```

✓ 0.6s



```
# set number of clusters
kclusters = 4

# run k-means clustering
kmeans = KMeans(n_clusters=kclusters, random_state=0).fit(toronto_onehot_grouped_clustering)

# check cluster labels generated for each row in the dataframe
kmeans.labels_[0:10]
```

9.8 - Create a DataFrame that contains the cluster labels, original data, and the top 10 most common Place Types for each postal code.

- Add the cluster labels to the toronto_onehot_sorted DataFrame.
- Create a copy of the original DataFrame.
- Merges the two DataFrames.

```
# add clustering labels
toronto_onehot_sorted.insert(0, 'Cluster Labels', kmeans.labels_)

toronto_onehot_merged = toronto_data_df

# merge toronto_grouped with toronto_data to add latitude/longitude for each neighborhood
toronto_onehot_merged = toronto_onehot_merged.join(toronto_onehot_sorted.set_index('Postal Code'), on='Postal Code', how='right')

toronto_onehot_merged.head() # check the last columns!
```

Open 'toronto_onehot_merged' in Data Wrangler

9.9 - Create the final Data frame using the toronto_onehot_merged, drop the columns not necessary for conclusion and discussion.

```
toronto_final = toronto_onehot_merged.drop(['Latitude', 'Longitude', 'Cafe Names'], axis= 1)
```

K-mean Cluster

Using the k-mean clusters, divided the dataset into 4 clusters based on the most common places types that comes into the assigned postal codes.

NEXT STEPS

The next iteration of our code will focus on expanding this data model both horizontally and vertically!

Horizontally, we can incorporate ethnicity data from Statistics Canada's 2021 census, adding another dimension to our market clustering model.

Additionally, we can incorporate more geospatial data to improve postal code zoning. The current radius-based method leads to overlaps, this will enhance accuracy.

Vertically, we can develop a decision tree to automatically identify the best market clusters for a cafe, taking into account various dimensions and suggesting optimal markets.
